To find Thevenin voltage and Norton current:

- $(R_{eq})$  Turn off all independent sources (dependent sources remain unchanged) and calculate the resulting resistance at the desired port. Notice that you may have to apply the i-v test if resistors cannot be combined through series and parallel connections, or if the circuit includes dependent sources.
- $(V_{th})$  Leave the desired port open-circuited (i.e. no load connected) and find the voltage across it.
- $(I_N)$  Short-circuit the desired port (i.e. connect a short circuit across the port) and find the current through it.
